WhatURL?! Bookmark helper is based on both the Eudora mailto helper by Christian Huldt, and the bookmark helper that comes with ICeTEe 2, and the URL->Netscape script that comes with WhatURL?!.

This simple applescript program is for the people that like ICeTEe 2's new feature of option-command clicking URLs to save them instead of launching them right away. And people that like using the WhatURL?! bookmark utility.

The latest version of WhatURL?! (version 10b1) has some applescripting ability, but nothing to handle the stuff ICeTEe 2 sends. This simple script fills that void, until WhatURL?! handles it internally.

Also included is a small script that will turn the bookmark helper app back into a running script file, so you can edit it with a script editor.

This program is in the public domain.

USING

- Make sure you have ICeTEe 2 installed.
- Set up Internet Config to handle the bookmark helper
 - In the Helpers area of InternetConfig
 - Add a new helper for type "bookmark" and this app
(Better instructions are included with ICeTEe 2)
- option-command-click away

HINTS

- Set this as your bookmark helper in the Internet Config application.
- If it doesn't work, rebuild your desktop.
- It generally works better when WhatURL?! is already running.
